Human Female European Skull

Product Number: BCM-891

Known Information:

This skull is associated with a skeleton of a 41-year-old European female, who stood 5' 6" and weighed 133 pounds at time of death. Cause of death was heart failure due to drug overdose. Information about this individual was documented at the time of her death.

Maxwell Museum of Anthropology:

The Maxwell Museum of Anthropology's Laboratory of Human Osteology, at the University of New Mexico, specializes in numerous facets of physical anthropology. The laboratory serves as a repository of human remains and includes prehistoric, historic, documented, and forensic remains.

Established in 1984 by Dr. J. Stanley Rhine, the Maxwell Museum's Documented Skeletal Collection has grown to include 237 individuals (as of July 2005) encompassing both sexes, all ages, and many population groups. The skeletal remains are obtained by donation, either by the individual before death, or by the family of a deceased loved one. Information on the sex, age, population affinity, and cause of death is available for the majority of these individuals, allowing students and visiting researchers to develop and test new techniques and theories.

Since 1995, prospective donors or their families have been asked to provide health and occupational data as well. With this information, researchers are able to examine the skeletal manifestations of particular diseases including degenerative joint and disc diseases, lymphoma, and osteoporosis, as well as the reaction of bone to repetitive motions and trauma. Recent research has included efforts towards the identification of handedness in individuals, determination of body mass from the skeleton, and variation in cranial damage from various projectiles. The importance of the Documented Collection cannot be overstated. No other institution in the American West has as large a collection of human skeletal remains with such extensive demographic data.

Bone Clones is grateful to the Maxwell Museum for allowing us to select specimens for reproduction from their valuable collection and granting us exclusive casting rights to these pieces.

Human Female European Skull

<u>Product Number:</u>	BCM-891-A
<u>Specimen Evaluated:</u>	Bone Clones® replica
<u>Skeletal Inventory:</u>	1 cranium with dentition 1 mandible with dentition

Dentition:

The skull exhibits full adult dentition with the exception of all of the 3rd molars. There is no evidence of carious lesions, dental abscessing, or excessive dental attrition.

Features of Sex:

Females tend to have smaller, slighter skulls than males. In this case, the morphology of the skull is consistent with that of the female sex. Various cranial characteristics were evaluated: the small mastoid processes, a sharp supraorbital margin, and the pointed mental eminence on the mandible (Buikstra and Ubelaker, 1994; Bass, 1995; White and Folkens, 2000). Note: The determination of sex was made in conjunction with an analysis of the pelvis.

Figure 1: The mastoid process is small, which is often the case in female skulls.

Features of Age:

The entire skeleton was available for analysis in the estimation of age. Since all of the permanent dentition was present, and epiphyseal union was complete, the skeleton was classified as an adult. It is also evident that very few degenerative changes have begun; therefore, this is not an elderly individual. The degree of cranial suture closure was one of the criteria used to estimate age, even though there is considerable variability in closure rates (Meindl and Lovejoy, 1989). The skeletal morphology is consistent with a middle-aged adult (35-45 years).

Features of Ancestry:

Several morphological traits of the skull were used to determine the European ancestry of this individual. For example, the nasal aperture is narrow/vertical, and there is poor dental occlusion (overbite), which are morphological traits indicative of an individual of European descent.

Figure 2: Narrow nasal aperture, which is indicative of European ancestry.

Figure 3: Poor dental occlusion indicates European descent.

SUMMARY:

(Note: Determinations are based upon examination of postcranial skeleton in addition to skull (see report for SCM-191-Report))

1. Sex: Female
2. Age: Middle-aged adult (mid-30s to mid-40s)
3. Ancestry: European

Educational Resources:

1. This skull displays some evidence of Asian traits, such as wormian bones, in addition to traits which are indicative of European ancestry. This makes this skull a good example for discussing the inter-mixing of ancestral groups.
2. This is an excellent example of an adult female skull. While in some circumstances the skull alone may be a reliable indicator of sex, the importance of examining the entire skeleton (particularly the pelvis) when assessing sex should be stressed. Integrating data from a variety of sources is a good practice, and it will give the most reliable results.
3. Estimating age is best accomplished through analysis of the entire skeleton rather than the skull alone. The degree of suture closure can be suggestive of an age range, but the great variability in closure rates must be recognized. Other morphological criteria, including the morphology of the pubic symphyses, are significant in age estimation.

Disclaimers:

This report is meant only as a teaching tool for introductory level students of the anatomical, anthropology, or forensic sciences who may be using this specimen to learn about human osteology. Evaluation of skeletal material is best done with original specimens. My evaluation was based solely upon studies of a Bone Clones® replica. My opinions are based solely upon the material presented to me. This is somewhat artificial as in real forensic or archaeological investigations, additional studies would be undertaken prior to the formulation of diagnoses and the production of a report. These studies might include plain film radiography, computed tomography (CT) studies, histology, etc. My opinions regarding sex and ancestry are based only upon non-metric analyses.
